

## Properties of pure substance.

### Introduction

- > Matter exist in different states. eg Ice, water and steam are 3 states of same species water.
- > Based on this we classify the different states a) Solid (b) liquid (c) gas.
- > The different states in which substance can exist is called phase.
- > A system which is uniform in chemical composition and physical state is called homogenous substance or phase.

### Pure substance

Pure substance is one which is homogenous and has a fixed chemical composition throughout its mass.

(Ex) Ice and water are in two phase system. A mixture of ice, water and steam is a pure substance or one component as the chemical composition is same.

(Ex) Air - Composition of  $N_2$  and  $O_2$   
Mixture of  $CO$  and  $O_2$

> The mixture of oil and water is not a pure substance since oil is not soluble in water.

A mixture of two or more phase of a pure substance is also called as pure substance.

# Phase change process of pure substance (water) or Steam formation.

Introduction

> Matter exist in different states of ice, water and steam

and 3 states of pure substance water.

> Based on this we (graph) first different states of pure

(b) liquid (c) gas

> The different states in which substance (water) is called phases.

> A process which is uniform in chemical composition

and homogeneous is called homogeneous phase or pure

substance. In our study is homogeneous and

substance. A mixture of two or more phases or one

substance is called heterogeneous mixture.

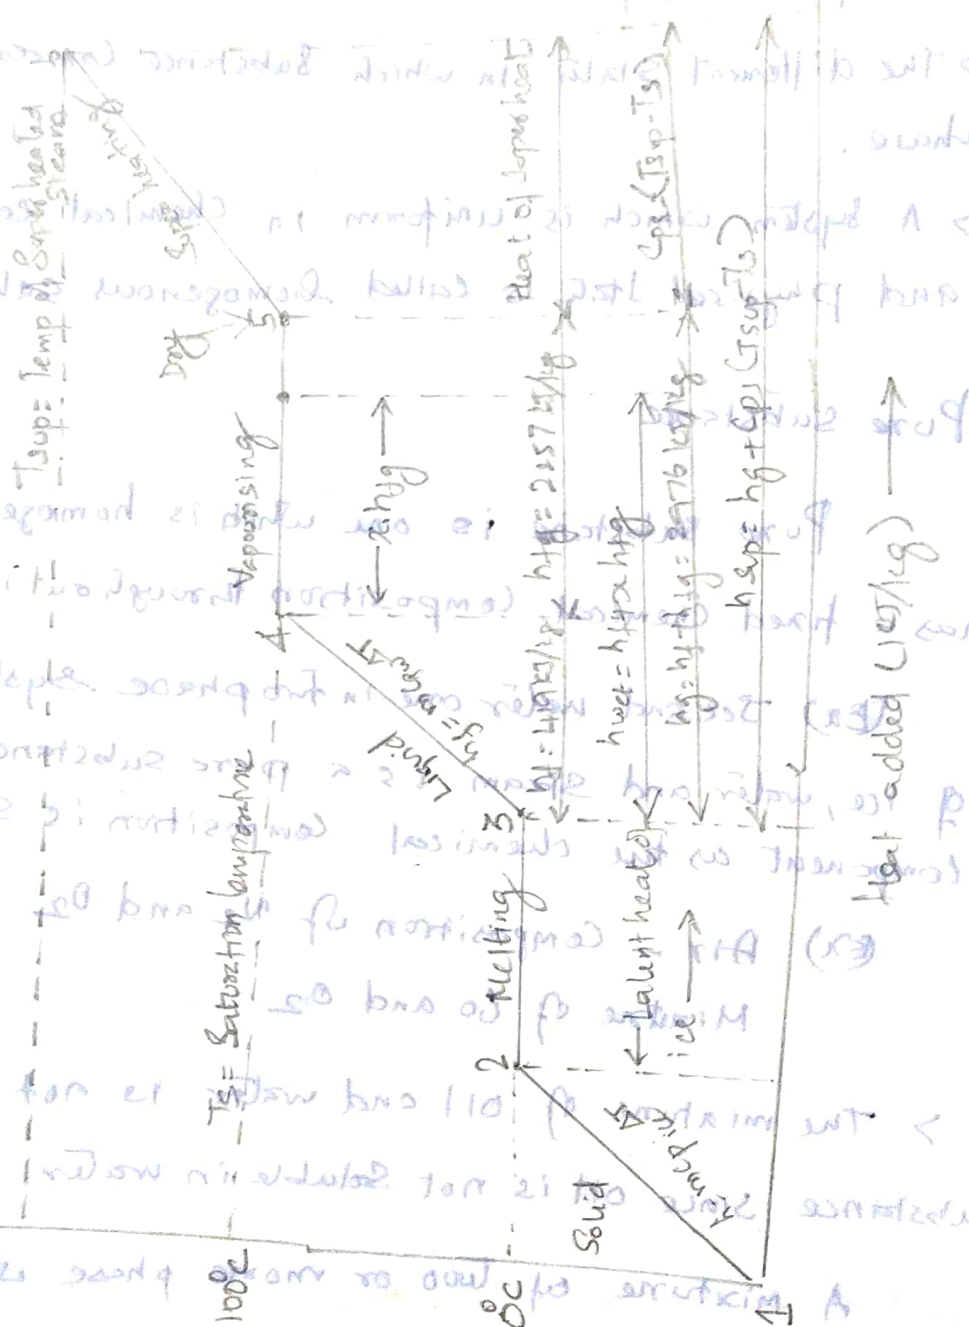

(a) All composition of solid and liquid

> The mixture of oil and water is not a pure substance

because it is not uniform in water

A mixture of two or more phases of a pure

substance is also called as pure substance (c)

Consider one kg of ice at  $-20^{\circ}\text{C}$  in a closed vessel under a pressure of  $P$  ( $\text{N/m}^2$ ). If we heat the water gradually when pressure remains constant, the following changes occur

### Solid Stage (1-2)

- > In this stage, Ice is ~~converted in water at constant temperature ( $0^{\circ}\text{C}$ )~~. It is gradually heated as temperature increases
- > Heat supplied is ~~latent heat of fusion~~ and when temperature reaches  $0^{\circ}\text{C}$  ( $273\text{K}$ ) ice begins to melt
- > Temperature is freezing point of ice or melting point

### Melting Stage (2-3)

- > In this stage Ice is completely converted into water at constant temperature ( $0^{\circ}\text{C}$ )
- > Heat supplied is latent heat of fusion or latent heat of ice.

### Liquid Stage (3-4)

- > On further heating, the water reaches its boiling point  $A$ .

> Saturation temperature is at which water begins to boil. ( $T_s$ )

> Heat supplied is liquid enthalpy or sensible heat of water. ( $h_f$ ) — heat added from  $0^{\circ}$  to  $100^{\circ}\text{C}$

$$h_f = mc_p(T_2 - T_1)$$

Boiling point of water is  $100^{\circ}\text{C}$ .

It is also called latent heat of water.

## Evaporation Stage (4-5)

> On further addition of heat beyond the point 4, water is gradually converted to steam.

> The steam contains some water particles in suspension and is called wet steam.

> On further addition of heat wet steam is converted into dry steam, or dry saturated steam.

> The amount of heat added is latent heat of vaporization or enthalpy of vaporization or enthalpy of steam. It is denoted by  $h_{fg}$ .

## Super heating Stage (5-6)

On further heating the temperature rises again.

The process is superheating and steam is known as the superheated steam.

> The heat supplied to the dry steam at saturation temperature is  $T_s$  and converted into superheated steam at temp ( $T_{sup}$ ) is called heat of super heat. It is

denoted  $h_{sup}$ .

$$h_{sup} = h_{fg} + C_p (T_{sup} - T_s) \text{ kJ/kg}$$

where  $C_p$  - specific heat capacity of water at constant

Pressure.
